

RHIC Technical Note No. 7

THE STATIONARY RF BUCKET

H. Hahn

August 28, 1984

Introduction

As a result of intrabeam scattering, the bunches in RHIC will fill the entire bucket during the normal operation period. It follows that in analyzing the related rf problems the full nonlinear theory is required. In the pertinent literature, the nonlinear solutions were obtained by numerical integration.¹⁻³ For stationary buckets the integration can be carried out leading to analytical expressions.⁴ In the present note, these expressions are rederived and used to produce numerical tables.

Synchrotron oscillation equations

The equations of synchrotron oscillations can be derived from the Hamiltonian

$$H(w, \phi) = |\eta| \frac{h^2 \omega_\infty^2 w^2}{\gamma E_0 A} - \frac{Q \text{ eV}}{2\pi h} \left\{ \cos\phi - \cos\phi_s + (\phi - \phi_s) \sin\phi_s \right\}$$

in the canonically conjugate energy variable w and position variable ϕ , which describe the motion around the synchronous particle (subscript s).

Following definitions apply:

$$w = \frac{\Delta E A}{h \beta \omega_\infty}$$

$$\omega_{\infty} = c/R_0$$

$$\omega_{rf} = h \beta \omega_{\infty}$$

$$\eta = \frac{1}{\gamma_{tr}^2} - \frac{1}{\gamma^2}$$

and

ΔE = energy deviation/amu

A = atomic mass unit

Q = charge state

E_0 = rest mass/amu.

The stationary bucket is defined by $\sin\phi_s = 0$ leading to

$$H(w, \phi) = |\eta| \frac{h^2 \omega_{\infty}^2}{\gamma E_0 A} \frac{w^2}{2} + \frac{QeV}{\pi h} \sin^2 \phi/2$$

The phase space trajectories are given by $H = \text{constant}$,

$$\left(\frac{w}{w_B}\right)^2 + \sin^2 \phi/2 = N \quad \text{for } 0 < N < 1$$

with the constant N known as the Cole-Morton parameter. The bucket half height ($N = 1$) is given by

$$w_B = \left(\frac{2}{\pi} \frac{\gamma E_0 eV}{|\eta| \omega_{\infty}^2 h^3} QA \right)^{1/2}$$

or, in terms of energy, by

$$\Delta_B = \left(\frac{\Delta E}{E} \right)_B = \left(\frac{2}{\pi} \frac{\beta^2 eV}{h |\eta| \gamma E_0} \frac{Q}{A} \right)^{1/2}$$

The dimensions of a partial bucket ($0 < N < 1$) are

$$\text{Half-height} \quad w_N = \sqrt{N} w_B$$

$$\begin{aligned} \text{Half-width} \quad \phi_N &= 2 \arcsin \sqrt{N} \\ &\approx 2 \sqrt{N} \quad \text{for } N \ll 1 \end{aligned}$$

Bunch half height and bucket half height are, therefore, related by

$$\Delta_E = \Delta_B \sin \phi_N/2$$

The stationary bucket factor

The phase space area/amu of a partial bucket is given by

$$\begin{aligned} A_N &= \frac{4}{A} \int_0^{\phi_N} w \, d\phi \\ &= \frac{4}{A} w_B \int_0^{\phi_N} (N - \sin^2 \phi/2)^{1/2} \, d\phi \end{aligned}$$

By means of the coordinate transformation

$$\sin \phi/2 = \sqrt{N} x$$

and the usual definition for the stationary bucket factor

$$\alpha_N = \frac{A_N A}{8 w_B}$$

one finds

$$\begin{aligned} \alpha_N &= N \int_0^1 \frac{(1-x^2)^{1/2}}{(1-Nx^2)^{1/2}} \, dx \\ &= (N-1) K(N) + E(N) \end{aligned}$$

with $K(N)$ and $E(N)$ the complete elliptical integrals of the first and second kind.

In the small-amplitude limit

$$\alpha_N \int_0^{\frac{\pi}{2}} \dots \quad N \ll 1$$

$$A_N \int_0^{2\pi} \dots = \pi w_N \phi_N$$

Furthermore $\lim_{N \rightarrow 1} \alpha_N = 1$

Synchrotron oscillation frequency

The period of one synchrotron oscillation

$$T = \frac{2\pi}{\Omega}$$

is obtained by integration of

$$\frac{d\phi}{dt} = \frac{\partial H}{\partial w} = 2 \Omega_0 \sqrt{N - \sin^2 \phi/2}$$

where the small-amplitude synchrotron oscillation frequency is anticipated, with

$$\Omega_0 = \omega_{\infty} \sqrt{\frac{|\eta| h e V Q}{2 \pi \gamma E_0 A}}$$

From

$$\int_0^{T/4} dt = \frac{1}{2\Omega_0} \int_0^{\phi_N} \frac{d\phi}{\sqrt{N - \sin^2 \phi/2}}$$

follows

$$\Omega_0 / \Omega = \frac{2}{\pi} \int_0^1 \frac{1}{(1-x^2)^{-1/2} (1-Nx^2)^{-1/2}} dx$$

and finally

$$\Omega = \frac{\pi \Omega_0}{2 K(N)}$$

In the small amplitude approximation

$$\Omega \simeq \Omega_0 \quad \text{for } N \ll 1.$$

as expected.
