Abstract

Spink is a spin tracking code for polarized spin 1/2 particles. The code tracks both trajectories in 3D and spin. It works using thick element modeling from MAD to track trajectories and thin element modeling based on the BMT equation to track spin. The code is written in Fortran77 and typically runs on a Linux platform, either sequentially or MPI-parallel.
Acknowledgments

*spink* has been around for several years. We used and still extensively use it in Brookhaven for polarized proton studies at the AGS and RHIC. The code has been exported and used in other laboratories, notably Jülich in Germany and RIKEN and KEK-JPARC in Japan.

Many peoples have contributed with discussions and actual work on the code, notably Haixin Huang, Nick Tsoupas, Mei Bai, Fanglei Lin at Brookhaven, Andreas Lehrach at Jülich and Meiqin Xiao at RIKEN. Nick D’Imperio (BNL) contributed in a fundamental way to the implementation of the GUI. Constant interest and support by Thomas Roser has been important for the success of the code.

Tracking spin has been always an important tool to understand and to resolve problems of the acceleration of polarized particles. For circular accelerators several code have been written to address full or in part some of the issues, such as *depol* by Ernest Courant (BNL), *snake* by Jean Buon (Saclay), *sprint* by MathiasVogt (DESY). Partly of fully implementation of spin tracking exist in other codes, like *MAD* (CERN) and *COSY-infinity* (Michigan).

*spink* is just another contribution.

1 Physical Principles

Spink, that may stand for ‘Spin Tracking’, is a spin tracking code for spin 1/2 polarized particles [1]. The six phase space coordinates for the orbit and three coordinate representing the cartesian components of the unitary spin vector are tracked. Orbit tracking is done by propagating the vector $\vec{r}$ through first and second order maps generated by MAD [2]. These maps are for “thick” elements. Spin tracking is done via “thin” elements spin rotation matrices.

The output of MAD is transformed by the pre-processor Mad_read to an input file (lattice descriptor) suitable for spink. Two versions of MAD are currently supported by mad_read: mad8c (CERN) and BNLMad (J.Niederer). Work is in progress to accept input from madX, which is the only version of MAD presently supported by CERN, see 7.1.

Spink sequentially tracks several particles, averaging the final results. This task can also be performed “trivially” on a parallel computer since the code has been implemented using the MPI library.

Spink uses MKSA units and canonical orbital phase space variables as used by MAD, namely

$$\mathbf{r} = \left( x, x' = \frac{p_x}{p}, y, y' = \frac{p_y}{p}, \Delta \phi = -c \Delta t, \frac{\Delta E}{pc} \right).$$

(1)

The spin is treated as a 3-dimension real vector

$$\mathbf{S} = (S_x, S_y, S_z).$$

(2)

We follow the ‘US accelerator’ coordinate convention with $x$ radial, $y$ vertical, and $z$ longitudinal, while in the spin literature $z$ is often taken as vertical.

Input and output of phase space are in [mm] and [mrad] for transverse coordinates, $(x, x')$, radial and $(y, y')$, vertical. In input units are [rad] for the longitudinal coordinate $\Delta \phi$ and [GeV] for the energy coordinate $\Delta E$. $\Delta \phi$ and $\Delta E$ are evaluated with respect to the phase $\phi_s$ and energy $E_s$ of a reference synchronous particle.

1.1 Orbit and spin tracking

Spink uses MAD thick elements matrices to track particle orbits to first order. For second order the code uses either second order MAD generated maps, or thin element representation of machine elements that would require high order transfer map representation, such as multipoles.

MAD transfer maps are written for coordinate units [m] and [rad] in the transverse phase space, [m] for the phase, since in MAD it is $\Delta \phi \rightarrow -c \Delta t$, and [0] for the energy coordinate, since in that code it is $\Delta E \rightarrow \Delta E/pc$. In spink we use MAD coordinates.

The propagation of the transverse coordinates of the beam through the lattice is done using the equation

$$\vec{r}_i^{(\beta)} = \sum_j R_{ij} r_j^{(\beta)} + \sum_{jk} T_{ijk} r_j^{(\beta)} r_k^{(\beta)}, \quad i, k = 1, 4$$

(3)

with $R_{ij}$ first order matrices, $T_{ijk}$ second order maps, and $\vec{r}^{(\beta)} = \vec{r} - \vec{r}^{(COD)}$ is the displacement in space and angle of the particle from the closed orbit. The propagation of the longitudinal coordinates is in particular discussed in Sec. 4.13.

The accelerator lattice used by spink can be static, i.e. read once from MAD and never modified, or dynamic. Two ways are implemented in the code to dynamically modify the lattice using tables: (a) reading from a table a list of MAD and mad_read produced lattice descriptors for different energies, in which case, once a given energy is reached during acceleration, the track initializer routine TrackInit, Sec. 4.5, will read the next lattice; (b) reading tables of K1 values of all quadrupoles, etc. and update the transport matrices accordingly, Sec. 4.15.

The propagation of the spin coordinates is done by $3 \times 3$ matrices for thin elements. Spin matrices are simply derived from the BMT differential equation for spin motion [3], [4]

$$\frac{d\mathbf{S}}{dt} = \frac{e}{mc} \mathbf{S} \times \left[ \frac{1}{\gamma} (G\gamma + 1) \mathbf{B} - \frac{G\gamma}{\gamma + 1} (\vec{\beta} \cdot \mathbf{B}) \vec{\beta} - \left( G + \frac{1}{\gamma + 1} \right) \vec{\beta} \times \mathbf{E} \right]$$

(4)
as described in Sec. ?? [5]. \( \mathbf{B} \) is the magnetic field, \( \mathbf{E} \) is the electric field in the laboratory frame, and \( \beta \equiv v/c \) is the relativistic velocity of the particle.

1.2 Siberian Snakes and Spin Rotators

Siberian snakes [6] rotate the spin by a fixed angle. They are essential devices in circular accelerators for polarized beams to break the periodic condition that produces spin resonances and polarization losses.

Spin Rotators are used to orient the spin in a given direction. They are important in polarized beam colliders, to orient the beam polarization longitudinally or transversely at a collision point.

In spink, snakes and rotators are modeled in three ways:

- Synthetic
- Table driven
- Analytic

A synthetic snake or rotator is optically a thin element represented in the \( \text{MAD} \) lattice by a unit transfer map. Angle of spin rotation \( \mu \) and angles of the rotation axis \( \phi \), longitude, and \( \theta \), latitude are given as input, Sec. 7.3.9, and Sec. 7.3.10.

A table driven synthetic snake is a thick element, optically represented by the elements of a \( 6 \times 6 \) matrix, tables(11) and (12), and by the three angles, as a function of the relativistic energy \( \gamma \).

Analytic snakes and rotators are represented by orbit and spin matrices obtained from analytic expressions, Sec. 4.18.

2 Flowchart

The flowchart of spink and its pre-processors is shown in Fig.1. To run the code, three actions are needed, in sequence:

1. Run \( \text{MAD} \) to generate the lattice descriptor. Presently it is \( \text{mad8c} \), as described in Sec. 7.1. \( \text{mad8} \) generates three output files: \( \text{runname.twiss}, \text{runname.echo}, \text{runname.madout} \). The first two files are always needed; the third is only needed if there are lattice errors.

2. With the names of these files inserted in the input file \( \text{mad_read.in} \), run \( \text{mad_read} \). This generates a lattice descriptor that combines the three files in one file \( \text{runname.sy} \), Sec. 7.2.

3. Using the GUI build the input file \( \text{spink.in} \) to \( \text{spink} \), and run \( \text{spink} \). These operations are conveniently done through a Unix script, Sec. 7.3.

The above flowchart only shows the main routines. Individual subprograms will be discussed in the following sections.

3 Include files

Two include files are supplied, \( \text{SpinkGlobal} \) and \( \text{SpinkName} \)

- \( \text{SpinkGlobal} \) contains the definition of data types for all the variables, integer, boolean, real, strings and also all the common blocks used in the program;

- \( \text{SpinkName} \) contains the namelist blocks, with the list of the input variables in the blocks. Input to spink is through namelist, contained in the input file \( \text{spink.in} \).
Figure 1: Flowchart of spink and its preprocessors
4  *spink* routines

4.1 routine *SpinkData*

In this subroutine variables are initialized.

4.2 routine *FOpen*

Open files and tables.

In this subroutine the following functions are performed

- Namelist blocks are read and parsed through a call to *NmlRead*, Sec. 4.3
- Input and output files are opened. All file names are arbitrary.
- There is a convention here: if a file name has a # (in the GUI), or a blank ‘ ’ (in *spink.in*), as a first character, the file is ignored. The opening of a file is equivalent to set a flag, boolean *fstat(n)=.true.* with n the number of the unit associated to the file. Some actions will be performed or not according to a file being open or not, as we will see later. If a file name starts with a ‘ ’ as a first character, the file is opened with access=append.
- Some actions of the code are driven by a table of values vs. turn number in the tracking or vs. values of the energy, when there is acceleration in the synchrotron, as it will be described later, Sec. 4.4. Tables are initialized (opened) in this routine, with the same conventions used for the files. For tables the status boolean flag is *tstat(n)*, with n the table number.
- Some initialization is performed in *FOpen*, in particular for subsequent averaging: entry *Param*, and entry *pInit*. The program run ends also here: entry *Finis*.

4.3 routine *NmlRead*

Read namelist input.

This routine, called from *FOpen*, serves the dual purpose to accept a namelist driver (input file *spink.in*) created by the GUI or a namelist file directly edited. The point is that in a namelist file created by a GUI some namelist blocks are missing, when the corresponding module is checked off. In this case, Fortran would signal an error in reading and stop execution. A solution to this problem\(^1\) is implemented in the present subroutine.

*NmlRead* has also a quick diagnostics to signal any error in reeding a namelist, a very common source of troubles, if *spink.in* is directly created by editing and not through the GUI.

4.4 routine *Tables*

Tables are being used in *spink* for functions or parameters that vary in the course of a run. Some tables use the number of turns as the independent variable (first column), some use the relativistic energy factor γ.

- The first line of a table contains an integer number: the number of columns after the first, for the rest this line is available for comments or a header.
- A table is read (opened) in the subroutine *FOpen*, Sec. 4.2. For tables we use the same convention as for files, namely if the first character of the table name is a # (GUI) or a blank ‘ ’ the table is ignored. Table names included in [ ] brackets (GUI) are intended to be name arrays.
- Tables are read in the entry *Tables:TableRead*, their content is temporarily put in a reserved buffer file, unit(11), and then stored in memory.

\(^1\)thanks to Len Slatest of BNL
• if the first column is turn number, table entries are stored as \( n\text{Tab}(k,j), v\text{Tab}(k,j,l) \) where \( k \) is the table number, \( j \) is the row number, \( l \) is the column number.

• if the first column in the table is \( \gamma \), table entries are stored as \( \text{gam}\text{Tab}(k,j), v\text{Tab}(k,j,l) \).

• A specific record in a table can be retrieved calling the entry \texttt{Tables:TableReadRecord}

• Interpolation (linear) in the tables is done by calling the entry \texttt{Tables:TableInterp}

• A variable value in the last row of the table can be retrieved calling the entry \texttt{Tables:TableInterpLast}

The GUI windows for tables is described in Sec. 7.3.4.

### 4.5 routine \texttt{TrackInit}

Track initialization.

The subroutine reads the \texttt{runname.sy} file created by the pre-processor \texttt{mad\_read} from MAD, as described in Sec. 7.2, and stores in memory values of the parameters.

• read 1.st record, for the entire lattice:
  1: version of MAD, order of tracking (1.st or 2.nd), flag for errors in the lattice (0/1), total number of machine elements.

• for each machine element, read records 2, 3, 4
  2: \texttt{el\_name} = element name, \texttt{el\_keyw} = keyword, or element type, a 4 character string
  \texttt{el\_len} = elem. length [m],
  3: \texttt{el\_ang} = bend angle, \texttt{el\_k1} = quadrupole gradient = \( -(\partial B/\partial r)/B \rho \) [m\(^{-1}\)],
  4: \texttt{el\_k2} = sextupole gradient = \( -(\partial^2 B/\partial r^2)/B \rho \) [m\(^{-2}\)], \texttt{el\_tilt} = tilt angle [rad],
  \texttt{el\_kickh} = horizontal kick [rad], \texttt{el\_kickv} = vertical kick [rad]

• for each element, read records 5, 6 if there are lattice errors:
  5: values of \texttt{el\_der} = displacement (\( \delta x, \delta y, \delta z \) [m]), angle errors (\( \delta \phi, \delta \theta, \delta \psi \) [rad]),
  6: values of field errors \texttt{el\_dk}.see MAD manual

• for each element, read record 7, if error, or 5:
  7 [5]: values for the Distorted Closed Orbit, \texttt{r\_cod} = x,y,z [m], and the longitudinal position of the element end, \texttt{s\_cod} [m].

• for each element, read records 8-13, if error, or 6-11:
  6 \times 6 orbit transport matrix \texttt{R\_mat}.

• for each element, if track order = 2, and error, read records 9-43, if no error read records 6-41:
  a 6 \times 6 \times 6 second order transport map \texttt{T\_mat}.

• finally, for the entire lattice:
  values of \texttt{mad\_tune} = betatron tunes \( \nu_x, \nu_y \), \texttt{gamtr} = transition gamma = \( \gamma_T \),
  \texttt{mad\_circ} = total length of the ring [m], 6 \times 6 one turn matrix \texttt{OT\_mat}.
Some *spink* keywords are not recognized by *MAD*. In this case, *TrackInit* uses their name as keyword. E.g. a (thin) Siberian Snake should be defined as a MARKER in *MAD*, with name SNAK as follows:

SNAK: MARKER

In *spink* both name and keyword will be SNAK.

Keywords used for different machine elements are

### 4.5.1 Betatron tune adjustment

This is a special features of *TrackInit*.

Each quadrupole in the ring is padded by two thin addional quadrupoles, that provide a fine adjustment of the machine tune. This is useful is some run when one may want to scan a small interval of tunes with no need to run *MAD* again for each tune.

The algorithm is contained in the subroutine *Tunes:Detune*.

### 4.5.2 Discarded elements

Sometimes the lattice contains many machine elements that do not rotate the spin and that we want to discard to expedite *spink* runs. *TrackInit* can find them on a file, unit(14), and just ignores them. This may save substantial run time.
4.6 **routine Track**

This is the most important routine in *SPINK*. **Track** is based on three nested loops

```
call SyncParticle  
{  
call WorkParticle  
call npInit  
{  
call nInit  
{  
call Orbit  
call Sprot  
}  
}  
call WriteOutput  
}
```

The propagation of the orbit vector $r$ is done in **Orbit**, Sec. 4.12, based on *MAD* maps, and the propagation of the spin vector $S$ is done in **Sprot**, Sec. ?? with spin matrices based on the BMT equation.

It is important to recall that *spink* deals with low intensity polarized beams, so all particles in the tracking are independent. The only interaction is done when averaging variables over all particles in the beam. *spink* is essentially a sequentially structured code, where each particle is treated separately, hence the outer ‘particle’ loop.

Since tracking on a large accelerator with many lattice elements may take a considerable time, the use of a multi process parallel platform is essential to determine ensemble results. Processors can be run independently, ”one case for each processor”. However, *spink* has also been implemented with the MPI library [7] for parallel computation. For this ”trivial” case MPI features must be enabled at compilation time, Sec. 7.4.

- The first call of **Track** is to **SyncParticle**, subroutine where the parameters of the reference (Synchronous) particle are set.

- The first call inside the particle loop (loop global variable $np$) is to **WorkParticle**, subroutine where the parameters of each individual particle in the simulation are set. This routine reads the coordinates of each Work Particle either defined on the contour of an ellipse of given emittance (see the GUI, variables for the module **Pop** and relative help string) or produced randomly by the subroutine **MakePop**, Sec. 4.8.

- Some variables are initialized per particle in the entry **npInit** in the subroutine **MiscInit**. If active, tables are at this point initialized by a call to the entry **TableInit** of the subroutine **Tables**, Sec. 4.4.

- Then, the loop on turns starts. In this loop the running variable is the $nt$ turn number in the synchrotron (a global variable). Another leading variable is $G\gamma$, where $G$ is the gyromagnetic anomaly of the particles ($G = 1.7928456$ for the proton and $=-0.14301$ for the deuteron) and $\gamma$ is the relativistic energy factor, ”energy”. A run is terminated at the maximum number of turns $n_{\text{turn}}$ or, alternatively, by the initial and final value of $G\gamma$, whichever is reached first.

- The first call in the turn loop is to Table(8). This table, if activated, contains a list of names of *MAD*-created input lattice descriptors of the machine and is used to update the lattice at intervals in energy, Sec. 4.4.

- Then, the One Turn Spin matrix is initialized by call to the entry **SpinGoodies:OneTurnSpinMatInit** and quantities per turn are initialized by the entry **MiscInit:ntInit**, in particular the counters for special lattice elements, like snakes, Sec. 4.7.
Then the loops on lattice elements starts. *Track* explores the lattice and finds all the elements, recognized by their keyword *el_keyw*, Sec. 4.5.

The phase space vector for the orbit is updated by the subroutine *Orbit*, Sec. 4.12, and the spin is updated by the subroutine *Sprot*, Sec 4.17. Calls to the diagnostic entry *Diagnostics:PrintAtElement* are done if the diagnostics file unit(99) is open.

The output is written to records when machine elements, specified in the input, are encountered, by the entry *Output:PrepareOutput*. The record will be written to the specific files (units(51, 52, 53, ...)) at turn end in the entry *Output:WriteOutput*.

Many other operations are performed at the end of each turn, like performing averages or calculate betatron tune and spin tune.

Similar operations are performed at the end of the other two external loops, turn loop, and particle loop.

### 4.7 routine MiscInit

Some variables must be initialized or re-initialized once per particle, once per turn and once per machine elements in the three nested loops of *Track*. This is done in *MiscInit* that has three entries:

- **entry MiscInit:npInit.** Initialization per particle. RFDipoles (tables(3) and (4)), Sec. 4.23, Froissart-Stora, Sec. 6.1, Spin Flipper, Sec. 4.24, and quantities to be averaged over many particles.

- **entry MiscInit:ntInit.** Initialization per turn of counters for helices, snakes, rotators, bumps, RF cavities, RF dipoles in the lattice.

  - HLX\_k, counter for helices
  - SNK\_k, counter for snakes
  - ROT\_k, counter for spin rotators
  - BMP\_k, counter for orbit bumps
  - RF\_k, counter for RadioFrequency cavities
  - RFDH\_k counter for horizontal RF Dipoles
  - RFDV\_k, counter for vertical RF Dipoles.

- **entry MiscInit:jelInit.** Initialize and re-initialize quantities per element, such that field components and orbit curvature to zero.
4.8 routine *Makepop*

Generates a random beam with KV, Water Bag, Linear, or Gaussian distribution in 6D, matched in transverse to alfa, beta, emittance (rms)\(^2\).

*Makepop* writes a particle distribution to unit(13), input file to *spink*. If this unit is read, it overwrites any distribution directly generated according to Sec. 7.3.8. Each record of the file associated to unit(13) contains the phase space and spin coordinates of one particle

\[(r, S) \equiv (x, x', y, y', \Delta \phi, \Delta E/pc, S_x, S_y, S_z)\]  

\(^{(5)}\)

4.9 routine *Popul8*

Function *Popul8* = *poprec*, where *poprec* is the string of Eq. (5) containing the phase space and spin coordinate of a particle to be used in *Track:WorkParticle*.

If any of the external population files, unit(13), generated by *Makepop*, Sec. 4.8, or unit(12), manually edited, is enabled, a record of the file is read into *Popul8* = *poprec*.

Otherwise, particle un-normalized transverse coordinates on an ellipse of emittance specified by input parameters, sec. 7.3.8 are created. The distribution is normalized to an invariant emittance in *WorkParticle*, Sec. 4.11.

In this latter case, the algorithm to generate \(n\) particles on a phase space ellipse is to put coordinates at equal angles of \(2\pi/n\), starting from the prescribed angle.

4.10 routine *SyncParticle*

Defines the synchronous (reference) particle in the beam. *SyncParticle* is the same for all particles, so it it is called before a particle (outermost) loop of *Track* is initiated.

Sets initial and final quantities for a track run. Calculates the synchronous phase on the basis of the prescribed energy gain per turn, from input, Sec. 7.3.6, or from acceleration table(1), if enabled, and from the total RF cavities’ accelerating voltage

\[\phi_s = \arcsin \frac{E_0 \gamma_s}{eV_{tot}}\]  

\(^{(6)}\)

4.11 routine *WorkParticle*

Reads the initial coordinates of a particle from *Popul8*, Sec. 4.9, and builds work particle parameters. If the flag *coup* is true, coordinates are interpreted in the Edward-Teng couple mode, call *Coup*, Sec. 4.26.

If a non zero closed distorted orbit (COD) is present, transverse coordinates \(rr\), absolute coordinate, and \(r_\beta\) coordinates with respect to the COD are established

\[rr_i = r_i^{(2)} + r_i^{(COD)}, \quad i = 1, 4.\]

Pendulum coordinates for the longitudinal motion are also initialized, Sec. 4.13.

\(^2\)After Giuliano Franchetti
4.12 routine *Orbit*

Orbital phase space propagation. The orbital motion of the particles in *spink* is controlled by subroutine *Orbit* called by *Track* at each element encountered in the lattice.

Algorithms are applied in the following order:

- Define a new phase space variable \( \mathbf{r}(^\beta) = \mathbf{r} - \mathbf{r}^{(COD)} \), i.e. the particle trajectory with respect to the COD orbit. 5.th and 6.th components of the COD vector are zero.

- Look for the element keyword, Sec. 4.5, and act accordingly. There is an entry for each type of element in the lattice.

- Call *RayTransfer* to propagate the phase space vector \( \mathbf{r} \) to the next element according to Eq. (3).

- Back transform the phase space vector \( \mathbf{r} = \mathbf{r}(^\beta) + \mathbf{r}^{(COD)} \)

*Beam-Beam* is recognized by name rather than keyword and is dealt with differently, Ssec. 6.2. So is *SpinFlipper*, Sec. 4.23

4.12.1 Treatment of lattice errors

If the machine lattice has errors, these errors are transmitted to *spink* via the *MAD* output file *runname.madout*, Sec. 7.1, read and processed by *mad_read*. Lattice errors are misalignments in the three directions, \( x, y, z \), and magnet errors, around axes oriented as \( x, y, z^3 \). To deal with misalignment (for spin dynamics vertical errors are especially important) the coordinates of a particle are displaced in *Orbit* with the opposite sign of the misalignment upon entering the element, and restored at the exit.

Similarly, the particle coordinate system should be rotated opposite to the rotation errors \(^4\).

---

\(^3\)There is an utility, *doom* of *madX* that automatically transfer measured magnet errors from a spreadsheet to *MAD*. This is an additional reason to migrate from *Mad8* to *madX*, Sec. 8

\(^4\)Element rotation is not yet implemented in *spink*
4.13 routine Acceleration

Longitudianl orbital phase space

When Track find a machine element whose keyw = RFCA, it increases the momentum of the synchronous particle according to the specified acceleration rate and the momentum of a working particle, proportionally to the applied RF voltage in the cavity. RFCA is an element type known to MAD. There can be several RF stations in the lattice, each with its voltage and harmonic number, as specified in the input, Sec. 7.3.6.

Acceleration can be done (1) at a constant rate (linear) by specifying in input the change of $\gamma$ per turn, or (2) reading a table of $\gamma$ vs. turn number (if such a table is open, the constant rate is overwritten).

The algorithms that are applied, are, in this order:

- Increase the energy of the synchronous particle

  $$E_s := E_s + \delta\gamma_s E_0,$$

  where $\delta\gamma_s$ is the increase of $\gamma$ per turn in the $i$-th cavity;

- Calculate the synchronous phase

  $$\phi_s = \arcsin \frac{E_0\delta\gamma_s}{eV},$$

  where $\delta\gamma_s = \sum \delta\gamma_s,i$ total variation of $\gamma$ per turn, and $eV = \sum eV_i$ total voltage in the cavities (vector sum);

- Transform the phase of the working particle being considered from the unit of $r(5) = -c\Delta t$, meters, to a unit of angle, radians

  $$\Delta\phi = -2\pi \frac{h_i\beta_s}{L} r(5), \quad (7)$$

  where $h_i$ is the harmonic number of the $i$-th cavity, $\beta_s$ is the relativistic velocity of the synch. particle, $L$ is the entire length of the accelerator;

- Check if the energy is above transition. In this case, apply a phase jump

  $$\phi_s := \pi - \phi_s, \text{ and } \phi := \pi - \phi$$

- Apply a step increase to the energy of the working particle, calculated as

  $$r(6) := r(6) + \frac{eV_i}{pc} (\sin \phi - \sin \phi_s), \quad (8)$$

  where the sixth phase space coordinate is $r(6) = \Delta E/pc$.

- Apply a kick to the transverse momenta of the particle

  $$p_x := \frac{p_x}{1 + \delta p/p}, \text{ and } p_y := \frac{p_y}{1 + \delta p/p}, \quad (9)$$

  where $\delta p/p = \delta\gamma_s/(\gamma_s\beta_s^2)$

The increment of energy per turn is subdivided in parts proportional to the voltage in each cavity

$$\delta\gamma_i = \frac{\delta\gamma_s}{\sum eV_i} eV_i$$

$^5$This kick produces a change in the amplitude of the transverse oscillation of the beam, so that the Courant-Snyder emittance of the beam changes by a factor $1/\sqrt{\beta\gamma}$ and the normalized emittance stays constant.
4.14 routine RayTransfer

This routine actually propagate the 6D phase space vector $r^{(\beta)}$ across a machine element. The equation implemented here is Eq. (3), to first and second order tracking.

Since second order tracking may be rather lengthy for large lattices, we may want to execute it only for certain machine elements, e.g. sextupoles. An input string corresponding to a class of elements, Sec. 7.3.17, switches on this action for that class. The string could be: NONE (no element tracked to second order), ALL (all elements to second), SEXT (only sextupoles to second), etc.

4.15 routine MatrixUpdate

Update matrices for a dynamical representation of the lattice using tables.

The general form of a first order transfer matrix with no coupling\(^6\) is

$$R = \begin{pmatrix} c_x & s_x & 0 & 0 & 0 & D \\ c'_x & s'_x & 0 & 0 & 0 & D' \\ 0 & 0 & c_y & s_y & 0 & 0 \\ 0 & 0 & c'_y & s'_y & 0 & 0 \\ E & E' & 0 & 0 & 1 & G \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix},$$

(10)

with $c, c', s, s'$ matrix elements for the transverse motion, $D, D'$ dispersion terms, $E, E'$ synchro-betatron terms, and $G$ the transition term, that can be defined through the momentum compaction. For a symplectic matrix it is $E' = -D, E = -D'$.

Entries of MatrixUpdate for different type of matrices are

- Entry MatrixUpdate:QuadMat. For a quadrupole whose name is found in table(9), the K1 strength vs. $\gamma$ is interpolated in the table and the $4 \times 4$ matrix transverse elements are updated. Note that to first order a quadrupole matrix has no dispersion terms, then no coupling between phase space variables $\phi$ and $\Delta E/pc$.

- Entry MatrixUpdate:DipoleMat. For a dipole with combined functions whose name is found in table(10), the K1 strength vs. $\gamma$ is interpolated in the table. The $4 \times 4$ matrix transverse elements are updated. this way. A dipole matrix has dispersion terms that are a function of energy, and also the transition element is a function of energy, namely

$$D = A/\gamma^2, \quad D' = B/\gamma^2, \quad G = C - H/\gamma^2,$$

with $A, B, C, H$ quantities defined in MAD [8].

- Entry MatrixUpdate:SnakeMat. For Siberian Snakes whose name is found in tables(11) and (12), two for the moment, the optics is changing with energy, so all the matrix elements should be updated according with the tables.

\(^{6}\)and for the most common case of a synchrotron entirely laying on a horizontal plane.
4.16 routine OneTurnOrbitMatrix

Update the OneTurnOrbitMatrix to calculate betatron tunes turn by turn.

Betatron tunes are calculated in *spink* with three methods, two of them based on counting orbit betatron oscillation, Sec. 4.25 or by an FFT of the orbit, Sec. 6.3. In the present routine betatron tunes (the fractional part of) are calculated from the eigenvalues of the one turn orbit matrix, so they are available turn-by-turn.

The routine has three entries:

- entry OneTurnOrbitMatrix:OTMatrixInit. Here, the one turn matrix is initialized at the beginning of a turn.
- entry OneTurnOrbitMatrix:OTMatrixUpdate. Here, the one turn matrix is calculated at each machine element by progressive multiplication of the element orbit matrices.
- entry OneTurnOrbitMatrix:FracTuneFromOTMat. Here, the fractional part of the betatron tunes is calculated from the trace of the one turn matrix.

4.17 routine Sprot

Spin rotation,

At variance with orbital phase space propagation, spin rotation $3 \times 3$ matrices are built on the fly, because spin rotation is a function of the magnetic field found at the instantaneous position of the particle. Spin matrices are constructed starting from the BMT Eq. (4), for thin elements [9]

$$\frac{dS}{dt} = \vec{\omega} \times S$$

where $\vec{\omega}$ is a function of the magnetic field calculated at the instantaneous position of the particle.

$$S_n = \sin \mu, \ C_s = 1 - \cos \mu$$

The Spin rotation matrix $S_{\text{mat}}$ is

$$M^{(S)} = \begin{pmatrix}
1 - (a_3^2 + a_2^2) C_s & a_1 a_2 C_s + a_3 S_n & a_1 a_3 C_s - a_2 S_n \\
 a_2 a_1 C_s - a_3 S_n & 1 - (a_1^2 + a_3^2) C_s & a_2 a_3 C_s + a_1 S_n \\
 a_3 a_1 C_s + a_2 S_n & a_3 a_2 C_s - a_1 S_n & 1 - (a_1^2 + a_2^2) C_s
\end{pmatrix}, \quad (11)$$

with

$$\begin{align*}
a_1 &= C \left[ (1 + G\gamma) B_x - G(\gamma - 1)(r' \cdot B) x' \right] \\
a_2 &= C \left[ (1 + G\gamma) B_y - G(\gamma - 1)(r' \cdot B) y' \right] \\
a_3 &= C \left[ (1 + G\gamma) B_z - G(\gamma - 1)(r' \cdot B) \right]
\end{align*}$$

$$\omega^2 = a_1^2 + (a_2 - 1/\rho)^2 + a_3^2, \quad \mu = \omega L .$$

$C = \frac{1}{L} (1 + x/\rho)$, $L$ is the length of a machine element, and the field components are calculated midway through the element.

Sprot is called by Track after Orbit and calls in turn SpinMat that produces matrices for different type of machine elements, Sec. 4.18. In the case of elements that do not rotate spin, like DRIFT or MARKER Sprot returns immediately to Track.
4.18 routine SpinMat

Spin Matrices.

The routine has many entries, for different types of machine elements. In this routine the magnetic field at the particle transverse position and in the middle of the machine element, $r_W$ is calculated and returned to $Sprot$.

- entry SpinMat:UnitSprot. Initialize a spin matrix as unitary.
- entry SpinMat:BendSprot. Spin rotation in a bend. If a bend is pure, i.e. has no gradient nor sextupole, its magnetic field is simply vertical and the entry returns with that component of the field. If the bend has multipoles, it returns to $Sprot$ but subsequently multipole spin rotation is called.
- entry SpinMat:MultipoleSprot. Magnetic field at the particle, for quadrupoles, tilt quadrupoles and sextupoles.
- entry SpinMat: SolenoidSprot. In good approximation the magnetic field of a solenoid is purely longitudinal.
- entry SpinMat:SnakeSynthSprot. For each Synthetic Siberian Snake in the lattice, in sequence (Snake counter $SNK_k$, with rotation angles given as input, Sec. 7.3.9, all coefficients for the spin matrix of $Sprot$ are calculated and returned.
- entry SpinMat:SnakeTabSprot. For a snake represented by a table, coefficients for spin matrix are calculated from angles in the table and returned to $Sprot$
- entry SpinMat:SpinrSynthSprot. Spin rotators, treated as for synthetic snakes, with rotation angles given as input, Sec. 7.3.10
- entry SpinMat:SprotInKicker. Calculate and return spin matrix elements in kickers, horizontal and vertical kicks.

For each element the global variable spin rotation angle $\mu \equiv m \mu$ is calculated.

4.19 routine Helix

Orbit and spin matrix for a helix based on some analytical description.

Some Siberian snakes and spin rotators are made with a sequence of helical dipoles [10]. Input parameters for a helix are the helix field, the helix pitch, the helicity sign (right- or left-handed), and the orientation of the field with the vertical. Parameters are entered through the GUI, Sec. 7.3.11, for their description. A counter $HLX_k$ numbers helices according to their occurrence while visiting the accelerator.

Helix has two entries:

- entry Helix:HelixOrbit. E.Courant model [11]. Here the beam transfer matrix elements are calculated, then the routine returns to Orbit.
- entry Helix:HelixSprotAnalyt. M.Syphers model [12]. Here the spin matrix elements are calculated, the routine returns to Sprot.
Some spin related quantities.

Entries are:

- **entry SpinGoodies:SpinInit**. Called from WorkParticle. Initializes spin components, after two of them (out of three) have been read from input, Sec. 7.3.8, or from unit(12) or (13) associated with the population file. Initializes One Turn Spin Matrix quantities for spin tune calculation.

- **entry SpinGoodies:SpinAngles**. Called from Track. Calculates and print on unit(33) (diagnostics file) the spin components and the angles of longitude and latitude of the spin vector along the orbit.

- **entry SpinGoodies:SpinSum**. Called from Track. For spin average over many particles, builds

  \[ \sum_{np} S(i), \quad \text{and} \quad \sum_{np} S(i^2), \quad i = 1, 3 \]

- **entry SpinGoodies:SpinTuneDo**, called from Track. Writes on unit(34) (diagnostics file) spin and spin cone data at the beginning of a turn and then collects and writes to (34) spin tune calculated from spin precession. Deprecated

- **entry SpinGoodies:SpinAverage**, called from Track. Calculates spin averaged by stroboscopic mean and variance over all particles at the end of each turn. Calculates and prints at the end of the run the angles of spin cone. If we want to center the input spin cone on the stable axis, we use

  the input spin cone of beam on stable axis, the stroboscopic averaged spin components are written on the input population file, unit(13), next to the phase space coordinates. In this entry also the average spin tune from the eigenvalues of the One Turn Spin matrix are calculated and printed to stdout at the end of the run.

- **entry SpinGoodies:SpinFileWrite**. Deprecated

- **entry SpinGoodies: OneTurnSpinMatInit**, called from Track. Initialize one turn spin matrix at the beginning of each turn. If unit(44) (diagnostics) is alive the stable axis is also initialized.

- **entry SpinGoodies: OneTurnSpinMatAtTurnEnd**, called from Track. If unit(30) (diagnostics), is alive, Calculate Spin One Turn matrix trace and stable axis components at turn end

- **entry SpinGoodies:SpinTune3**. Called at turn end. Calculate spin One-Turn variables between points of same phase space by averaging spin tune over turns (stroboscopic average). There is an approximation to calculate spin tune in one spin one-turn and re-normalize the One Turn Spin Matrix.

- **entry SpinGoodies:StoreSpinSum**. Store spin and tune sums at marker #1 for sequential average over particles. Write and read spin to unit(24), use unit(91) (disposable) as buffer. Write and read spin tune to unit(25), use unit(92) (disposable) as buffer.

- **entry SpinGoodies: MultiPartAverage**. Averages spin and tune values at marker #1 over all npart particles at run end. Writes results for spin average to unit(24) and spin tune average to unit(25).

---

7 This file will be used in a next run.
8 An exact one-turn for spin is when the particle is back in phase space where it started. It may take many accelerator turns because of betatron motion.
4.21 routine Bumps

Orbit Bumps

Orbit bumps are sometimes used on circular machines for special purposes. An example are the horizontal orbit bumps to offset the orbit in a helical Siberian Snake[13]. Orbit bumps must be represented by RayTransfer matrices for the orbital motion as well as by Spin matrices, because they generate a spin rotation. Bumps are called in sequence, with counter $BMP_k$.

Bumps has two entries

- entry $Bumps$:BumpOrbit. Bumps effect on orbit. Called from $Orbit$ for the orbital motion. Uses bump table(7). Bumps may be horizontal and vertical. Angle kicks on $p_x$ or $p_y$, respectively.

- entry $Bumps$:BumpSprot. Bump effect on spin. Called from $Sprot$ for the spin motion. Bumps may be horizontal and vertical. Spin matrix elements are calculated and returned.

4.22 routine Output

Prepares and prints out tracking output files.

$spink$ can generate several output files, for orbit and spin coordinates at given location around the ring. Each location (here a MARKER) is tagged by the $eLname$ of an element in the lattice. The list of print location is an input to the code.

- The entry $Output$:PrepareOutput is called at each one of the markers as they are found in the lattice during the element loop in $Track$ and a record containing the variables at the marker is written for each marker (up to 9). In this entry, also the transverse Courant-Snyder invariants for the beam are calculated and recorded$^9$

$$
\epsilon_n = \frac{\gamma_T u^2 + 2\alpha_T uv + \beta_T v^2}{\sqrt{\beta_T}}, \quad \text{with} \quad u, v = x, x', \quad \text{or} \quad y, y',
$$

with $\alpha_T, \beta_T, \gamma_T$ Twiss parameters, and $\beta, \gamma$ relativistic factors

- In the entry $Output$:WriteAtMarkers spin information can be written to a special file, unit(29).

- The entry $Output$:WriteOutput is called at give print intervals, Sec. 7.3.6, where output files, units(51)...(59) are written, one for each marker.

- Other files are written by the latter entry:
  - unit(40), spin rotation in the snakes,
  - unit(20), containing betatron tune and spin tune,
  - unit(30), containing stable spin axis components, calculated from the One Turn Spin Matrix, and the projection of the spin vector on that axis.

$^9$These quantities must remain constant if the tracking is correct, or equivalently the emittances must decrease as $(\beta\gamma)^{-1/2}$
Radio frequency dipoles

The formalism is due to Mei Bai [14]. An RF Dipole gives a RF kick to the beam and produces both an orbit bump and a spin rotation. Input parameters are the integrated magnetic field strength $B_{dl}$, in [Tesla.meter] and the RFD tune $\nu_m$. The orbit kick and phase are given by

$$K = \frac{B_{dl}}{B_p} \cos \phi + \text{phase}, \quad \phi = 2\pi \int \nu_m.$$

The kick is applied to the beam, either in the horizontal or vertical direction, as

$$p_x := p_x - K, \quad \text{or} \quad p_y := p_y - K.$$

The spin rotation angle is

$$\mu = (1 + G\gamma) K$$

and the spin rotation matrices are

$$\sigma_H = \begin{pmatrix} \cos \mu & 0 & \sin \mu \\ 0 & 1 & 0 \\ -\sin \mu & 0 & \cos \mu \end{pmatrix}, \quad \sigma_V = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos \mu & \sin \mu \\ 0 & -\sin \mu & \cos \mu \end{pmatrix},$$

for the horizontal and vertical plane, respectively.

Each RF Dipole must appear in the MAD description as elements with name RFDH or RFDV and type MARKER. Since MAD doesn’t have those element types, the routine TrackInit recognizes the name (el\_name) and convert it into a keyword (el\_keyw) RFDH or RFDV, Sec. 4.5.

When Track find in the lattice a machine element with el\_keyw = RFD, the RFD action is modeled in two routine entries: RFDipole:RFDOrbit, that calculates and applies a kick to the orbit, and RFDipoleRFDsprot, that calculates and applies a kick to the spin.

Reference value for $B_{dl}$ and $\nu_m$ and phase are given as input, Sec. 7.3.16. The arrays of value refer to the first, second, ... RFD found in the lattice. In the example, only the second RFD found is active.

RF Dipoles are activated by enabling table(3) and (4). for an horizontal field RFD, and for a vertical field RFD, respectively. After a first row containing the number of columns-1 to be read by TableRead, an RFD table contains, for each dipole turn number, a multiplier for RFD\_BdlMax, a multiplier for RFD\_tune\_m0.

An example of table for two RFDV’s (RFDV.tab, for the example above) is the following

<table>
<thead>
<tr>
<th>turn</th>
<th>1st dipole</th>
<th>2nd dipole</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>Bdl</td>
<td>0.000000</td>
</tr>
<tr>
<td></td>
<td>tune</td>
<td>1.000000</td>
</tr>
<tr>
<td>300</td>
<td>phase</td>
<td>90.</td>
</tr>
<tr>
<td>3300</td>
<td></td>
<td>90.</td>
</tr>
<tr>
<td>9300</td>
<td></td>
<td>90.</td>
</tr>
<tr>
<td>12300</td>
<td></td>
<td>90.</td>
</tr>
<tr>
<td>13300</td>
<td></td>
<td>90.</td>
</tr>
<tr>
<td>20000</td>
<td></td>
<td>90.</td>
</tr>
</tbody>
</table>

In the example, the kick is linearly built between turns 300 and 3300, stays constant between 3300 and 9300, and linearly decays to zero between 9300 and 12300. Any shape is possible, since TableInterp interpolates between values in the table.

If activated, two files are written, for RFDH, unit(35), and for RFDV, unit(36), containing columns of

$nt \quad Bdl \quad \nu_m \quad \phi \quad \text{Kick}$
4.24 routine *SpinFlipper*

This is for a Radio Frequency spin flipper. A Rf field is applied to the beam and generates a rotation of spin around an axis in the horizontal x-z plane, or the axis of a RF solenoid. The frequency may sweep through the resonant condition or, in the case of the solenoid may remain constant. The temporal shape of the applied field can be prescribed my means of table(13).

SpinFlipper has one entry

- SpinFlipper:SFSprot, called from Sprot. Specify as input, Sec. 7.3.14, at what turn to start action, the value of the integrated field Bdl, the spin flipper frequency, the frequency variation per turn, and how the field is applied, whether rotating or transverse, in x or y. or oscillating longitudinally (solenoid).

SpinFlipper calculates and returns to Sprot the spin matrix elements.

4.25 routine *Tunes*

Calculate tune and detune from betatron oscillations zero counts.

It is one of the methods to calculate betatron tunes. A better one, turn-by-turn, is to calculate betatron tunes (fractional part of) from the eigenvalue of the orbital one turn metrix. Tunes has 5 entries:

- entry Tunes:TuneInit. Initialize tune average over particles.
- entry Tunes:CountBetaZero. Count orbit zero crossings for tune evaluation, or comparing a tune oscillation wavelengt with the circumferende of the ring.
- entry Tunes:BetaTuneDo. Calculate betatron tune for each particle at end of run.
- entry Tunes:TuneAverage. Average tune for many particles
- entry Tunes:Detune, called by TrackInit, Sec. 4.5. Padding quadrupoles with two thin quads to obtain detuning. Every quadrupole transport matrix is transformed as follows

\[
\begin{align*}
R_x &= \begin{pmatrix} R_{1,1} - \frac{1}{4} R_{1,2} \delta q & R_{1,2} \\ R_{2,1} - R_{1,1} \delta q + \frac{1}{2} R_{1,2} \delta q^2 & R_{2,2} - \frac{1}{2} R_{1,2} \delta q \end{pmatrix} \\
R_y &= \begin{pmatrix} R_{3,3} + \frac{1}{2} R_{3,4} \delta q & R_{3,4} \\ R_{4,3} + R_{3,3} \delta q + \frac{1}{4} R_{3,4} \delta q^2 & R_{4,4} + \frac{1}{2} R_{3,4} \delta q \end{pmatrix}
\end{align*}
\]

with \( \delta q \) a (small) detuning parameter given in input, Sec. 7.3.6.

4.26 routine *Coup*

After the formalism of Edwards and Teng [15] [16]

If the boolean flag couple = .true. after the introduction of a few matrices based on the One Turn Matrix (OTM), we end up building a 4 x 4 matrix EDR that is being used in WorkParticle to transform the coupled input phase space coordinates \( \mathbf{u} \) to \( \mathbf{r} \)

\[
\mathbf{r} = \mathbf{EDR} \cdot \mathbf{u}.
\]

The latter equation is in WorkParticle
5 Diagnostics routines

5.1 routine Diagnostics

Various debugging diagnostics.

Diagnostics has three entries:

- entry Diagnostics:PrintAtElement. Print at element for turns between \( nt_{pr \_0} \) and \( nt_{pr \_1} \), given as input, Sec. 7.3.6. If unit(99) is open many relevant dynamic quantities, including phase space particle position \( \vec{r} \) and spin \( \vec{S} \), are printed element by element for a limited number of turns (1) before Orbit, (2) before Sprot, (3) after Sprot.

- entry Diagnostics:PrintAllMatrices. Print all orbit matrices at a certain energy on unit(42). Deprecated.

- entry Diagnostics:PrintStatusAtTrackEnd. Write phase space and spin at end of track on unit(43).

5.2 routine Sequence

Track and profile call sequence and spink flow.

Activate at compilation time with the directive SEQ=true.

6 Additional routines

6.1 routine FroissartStora

Polarization loss crossing an isolated spin resonance is well modeled by the Froissart-Stora formula [17]

\[
P_2 = P_1 \exp \left( -\frac{\pi \epsilon k^2}{2 \alpha} \right) - 1,
\]

where \( P_2 \) is the polarization after the resonance and \( P_1 \) is the pol. before the resonance, \( \epsilon \) is the resonance strenght and \( \alpha \) the speed of resonance crossing. Conversely, the formula can be used to calculate the resonance strenght by knowing \( P_2/P_1 \).

This is what is done in this routine. We specify in input, Sec. 7.3.13, at what energy FroSto\_Ggam we want to do this, and after how many turn we want to look at \( P_2 \) and the routine calculates the resonance \( \epsilon_k \) and writes it to stdout.

6.2 routine BeamBeam

In a collision between two beams of polarized hadrons, the particles in both beams suffer a deflection and also the polarization may change due to the motion of a polarized particle in the field of the other beam. In BeamBeam these effects are simulated by studying the kicks on orbit and spin of a particle in the field generated by a distribution, assumed Gaussian, of the other counterstreaming beam [18]. It is the so-called 'weak-strong beam-beam scenario'. Collision happen at a location specified in input, Sec. 7.3.15, coincident with one of the lattice elements, e.g. a marker. We specify also at what energy we want BeamBeam to occur and the number of particles in the beam.

BeamBeam contains three entries:

- entry BeamBeam:BBCoast. Slow down acceleration. Gradually turn on beam-beam. We want to see the effect on a coasting beam.

- entry BeamBeam:BBOrbit. Calculate Beam-beam orbit matrix -angle kick.

6.3 routine **OrbitFFT**

Betatron tune an orbit harmonics content is calculated by FFT. First, sample orbit at equal intervals, then calculates tune using routines `four1.fft` and `twofft.f` from 'Numerical Recipes in Fortran' [19] that are included..

6.4 routine **MPIOutput**

Output for parallel computing with the MPI (Message Passing Interface) library.

To use MPI the boolean at compilation time is `USEMPI = true`. Each particle in the simulation is assigned a rank number $my\_rank$, is individually tracked, and the results are averaged on the fly, at variance with sequential averaging were the averages are completed at run end. It is a trivial parallelization$^{10}$. If there is only one particle and one process, as for sequential average, the rank of the particle is $my\_rank=0$.

After a first block where spin averages are done, the routine presents two entries

- entry **MPIOutput:MPILogRec**. Write to Internal records initial and final parameters for each macro.

- entry **MPIOutput:MPILogOut**. Retrieve and write to log file 7 initial and final parameters for each macro

6.5 routine **Clock**

Set clock to measure run time for the first particle in a run. Enable in input, with `cclock=.true`. Sec. 7.3.5.

7 Pre Processors

7.1 **mad8**

At present use **mad8**. Work is in progress to accept input from **madX**.

Run with the command

`=> mad8c runname.mad`

The driver file `runname.mad` will produce the following

- A `runname.twiss` file containing the Twiss functions calculated at the physical end of each machine component and the distorted closed orbit COD, generated by the **mad8** command

  TWISS, tape=`runname.twiss`

- A `runname.echo` file$^{11}$, that contains the first and second order orbit transfer maps, generated by the command

  SELECT, FLAG=first [second], RANGE=#S/#E

- A `runname.madout` file, containing tables of misalignment and field errors in the machine elements (if any), generated with the commands

  PRINT, RANGE=#S/#E

  SELECT, ERROR ; EPRINT, RANGE=#S/#E

`runname.twiss`, `runname.echo` `runname.madout` constitute the input to **mad_read**.

$^{10}$A better use of a parallel computer is in the parallelization of some algorithm or, in particular in the case of high intensity beams, in the study of space charge effects on beam dynamics and polarization

$^{11}$The echo file was originally meant for diagnostics. Luckily it can contain the transport maps
7.2 mad_read

mad_read reads and combines the three MAD output files to create a single file runname.sy that contains Twiss functions, transfer maps, COD and information about machine component misalignment or field errors. If there are no errors, only the first two files are needed. All namefiles must be included in the driver file for mad_read.in.

The program is run with

=> mad_read < mad_read.in

The symplecticity of the matrices translated from MAD to runname.sy is improved with the use of an iterative algorithm and routine due to F.Neri.

The arrangement of runname.sy is as follows:

First record contains:

1  Mad vers.,  track order [=1 or 2]  errors [= 0 or 1]  n# of elements [= jel]

If track order = 1, and no errors, for each machine element a block of 12 lines follows:

<table>
<thead>
<tr>
<th>2</th>
<th>el. #</th>
<th>name</th>
<th>keyword</th>
<th>length</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>angle</td>
<td>K1</td>
<td>K2</td>
<td>tilt</td>
</tr>
<tr>
<td>4</td>
<td>orbit - 4 values (deprecated)</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>( \alpha_x )</td>
<td>( \beta_x )</td>
<td>( \mu_x )</td>
<td>( D_x )</td>
</tr>
<tr>
<td>6</td>
<td>( \alpha_y )</td>
<td>( \beta_y )</td>
<td>( \mu_y )</td>
<td>( D_y )</td>
</tr>
<tr>
<td>7</td>
<td>COD - 4 values</td>
<td>s coord.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>8-13</td>
<td>6 x 6 transfer matrix ( R_{mat} )</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

If track order = 2, and no errors, 36 lines follow for each block, containing the elements of \( T_{mat} \):

14-50  6 x 6 x 6 second order transfer map elements

If there are errors, after line 3 there are two lines containing position and angle errors, and field errors (see MAD for the description)

| 3a | \( \delta x \) | \( \delta y \) | \( \delta z \) | \( \delta \phi \) [pitch] | \( \delta \theta \) [yaw] | \( \delta \psi \) [roll] |
| 3b | \( \delta B \) | \( \delta K1 \) | \( \delta K2 \) | \( \delta K3 \) |
7.3 GUI

SPINK is launched through a motif-window based GUI. The GUI is a convenient interface to set values for the variables in the program, and to minimize errors of transcription.

At the prompt, the GUI is started with the command

```bash
=> uspink [runname]
```

where `uspink` is a C-shell Unix script and `runname` is an arbitrary name for the run. If a configuration file `runname.conf` exists because it has been previously created, a menu window with 3 buttons shows up, as in Fig. 2. If the conf file does not exist you will be warned.

To edit the configuration file, click on Setup: a windows containing a list of the modules of SPINK will appear, Figs. 3, for 18 modules.

On this, and on each of the other module editing windows there is a help button that comments the meaning of each variable, string or Boolean parameter. The variable names are the same used in the actual code. When finished with editing, go back to the start GUI window of Fig. 2 (still open on the screen) and select Store.

There is also another button, Load, that allows the user to load into the GUI the values of another configuration file previously created.

When finished with the GUI, close the window with the upper right cross. The script will convert the config file to a namelist input `runname.spink.in` and run SPINK.

One can also run directly SPINK, if you have already the `spink.in` file as follows

```bash
=> spink < spink.in
```

We will now visit all modules (GUI windows) that will be opened by clicking on edit, with detailed explanation of the meaning of all variables.

### 7.3.1 GUI: input files

The GUI windows for input files is shown in Fig. 4, left. Some filenames in the example have a # as a first character. These files will not be opened. An array of values is indicated by a [...]

File names are arbitrary. Files whose first character is # are ignored.

<table>
<thead>
<tr>

<td>string array</td>
<td>SEXT SNAKE</td>
<td>Machine elements to be tracked to second order options: el_names, NONE, ALL</td>
</tr>
</tbody>
</table>
7.4 Compilation and Run

For portability, SPINK has been written in Fortran77. The code makes use of include files that contain Global and Local variables, Common and Namelist definitions, so it is very easy to add and subtract variables.

The Spink source is being distributed through a directory that contains also a makefile for compilation. The code has been run on different Unix platforms, but it is advisable to recompile it when it is imported to a new computer.

The code is write protected through RCS, so a user who would like to modify or add to it should first check out a routine with the command

```bash
=>co -l routinename.F
```

and after the file has been modified, check it in again with

```bash
=>ci -u routinename.F
```

For sequential run of the code, the compilation is done (in Linux) with the gnu compiler

```
g77
```

and for parallel code with the compiler and directive

```
mpif77 -DUSEMPI
```

Of course one can use other compilers in different machines.

To compile, do

```bash
=>[make cleanall] , for the first time, then =>make
```

To run the code through the GUI (recommended), invoke

```bash
=>uspink runname
```

To run the code directly

```bash
=>spink < spink.in
```

where spink.in is the driver file containing namelist blocks.

8 Suggested improvements

SPINK is still under development and probably will always stay in this state. Immediate and not-so immediate improvements are

1. Since madX is currently supported at CERN, while mad8 is not any more, modifying mad_read to work with the former lattice generator seems a clear choice.

2. The present code works with thin spin rotation elements. This approximation seems well adequate to deal with large storage rings, like RHIC. For smaller machines thick spin elements are preferable. Already for tracking in the AGS we found that subdividing the bends in a few parts give results more in accord with experimental data.

3. Dynamic representation of the lattice. This is already implemented in the code in two different ways as explained in this manual. However, a real smooth implementation using tables is not yet working as we would like.

4. More work is needed for a complete characterization of the spin stable axis, stroboscopic averaging, and other spin goodies.

5. Tracking other particles and other spin states. Tracking vector and tensor polarization will require dealing with spin matrices with more dimensions.

6. Spin motion in the self field of intense beams may become an important issue for high luminosity colliders. This problem is addressed in SPINK in the BeamBeam routine, but a real study will require a large effort. For multi particle intense beam dynamics simulation an effective non-trivial parallelization is a must.
